Computer and Network Security

Amr El Mougy
Reham Ayman
Abdelrahman Anwar

Lecture (2)

Cryptographic Tools

Early History

- ❑ Egypt (Old Kingdom), ca. 1900BC. Use of non-standard hieroglyphs (probably not a serious attempt at secret communication)
- ❑ Mesopotamia, ca. 1500BC. Encrypted recipe for pottery glaze on clay tablet
- ❑ Hebrew, ca. 500BC. Monoalphabetic substitution cipher used by scholars

Not so Early History

- ❑ 800AD. Early description of frequency analysis for breaking substitution ciphers (credited to Arab mathematician Al-Kindi, 801–873). Works about cryptanalysis of single- and polyalphabetic ciphers
- ❑ Ahmad al-Qalqashandi 1355–1418 List of ciphers in his encyclopedia contains a cipher with multiple substitutions for each letter; frequency tables for letters to aid cryptanalysis
- ❑ 1467: Leon Battista Alberti (“father of Western cryptology”) describes the polyalphabetic cipher

Recent History

- ❑ WWII heavy use of **rotor machines** for complex **polyalphabetic substitution ciphers**

The “Enigma” machine:

Recent History

- ❑ The time of **WWII** brought massive advances in cryptography as well as cryptanalysis
- ❑ In the 20th century, **mathematical cryptography** was developed
 - Works by **Claude Shannon**. Any theoretically unbreakable cipher must have keys which are at least as long as the plaintext and used only once (one-time pad)
 - Publication of the **Data Encryption Standard** in 1970
- ❑ 1976 Ground-breaking paper: Whitfield **Diffie** and Martin **Hellman**. “New Directions in Cryptography” solves key exchange problem and sparks development of **asymmetric key algorithms**

Classical Substitution Ciphers

- ❑ Where letters of plaintext are **replaced** by other letters or by numbers or symbols
- ❑ Or if plaintext is viewed as a sequence of bits, then substitution involves **replacing plaintext bit patterns with ciphertext bit patterns**

Caesar Cipher

- ❑ Earliest known **substitution cipher** (invented by Julius Caesar)
- ❑ First attested use in military affairs
- ❑ Replaces each letter by 3rd letter down in the alphabet. Example:

Meet me after the toga party

PHHW PH DIWHU WKH WRJD SDUWB

- ❑ Can define transformation as:

a b c d e f g h i j k l m n o p q r s t u v w x y z
D E F G H I J K L M N O P Q R S T U V W X Y Z A B C

- ❑ Mathematically give each letter a number

a b c d e f g h i j k l m n o p q r s t u v w x y z
0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25

- ❑ Then have Caesar cipher as:

$$c = E(p) = (p + k) \bmod (26)$$

$$p = D(c) = (c - k) \bmod (26)$$

Breaking Caesar Cipher

- ❑ Only have 26 possible ciphers
 - ❑ A maps to A,B,..Z
- ❑ Could simply try each in turn
- ❑ a **brute force search**
- ❑ Given ciphertext, just try all shifts of letters
- ❑ Do need to recognize when have plaintext
- ❑ Compression reduces chance of breaking

Monoalphabetic Cipher

- ❑ Rather than just shifting the alphabet, shuffle (jumble) the letters arbitrarily
- ❑ Each plaintext letter maps to a different random ciphertext letter
- ❑ Hence key is 26 letters long

Plain: abcdefghijklmnopqrstuvwxyz

Cipher: DKVQFIBJWPESCXHTMYAUOLRGZN

Plaintext: ifwewishtoreplaceletters

Ciphertext: WIRFRWAJUHYFTSDVFSFUUFYA

- ❑ Now have a total of $26! = 4 \times 10^{26}$ keys
- ❑ With so many keys, might think is secure
- ❑ But would be **!!!WRONG!!!**

Breaking the Monoalphabetic Cipher

□ Given ciphertext:

UZQSOVUOHXMOPVGPOZPEVSGZWSZOPFPESXUDBMET SXAI Z
VUEPHZHMDZSHZOWSFPAPDTSVPQUZWYMXUZUHSX
EPYEPOPDZSZUFPOMBZWPFUPZHMDJUDTMOHMQ

Breaking the Monoalphabetic Cipher

- ❑ Human languages are **redundant**, eg “secrty s awsm”
- ❑ letters are **not equally commonly used**
- ❑ In English E is by far the most common letter
 - ❑ followed by T,R,N,I,O,A,S
- ❑ Other letters like Z,J,K,Q,X are fairly rare
- ❑ Have tables of single, double & triple letter frequencies for various languages

Breaking the Monoalphabetic Cipher

- Key concept - monoalphabetic substitution ciphers **do not change relative letter frequencies**
- Discovered by Arabian scientists in 9th century
- **Calculate letter frequencies** for ciphertext
- **Compare counts/plots** against known values
- If Caesar cipher look for common peaks/troughs
 - peaks at: A-E-I triple, NO pair, RST triple
 - troughs at: JK, X-Z
- For monoalphabetic must identify each letter
 - **tables of common double/triple letters help**

Breaking the Monoalphabetic Cipher

- Given ciphertext:

UZQSOVUOHXMOPVGPOZPEVSGZWSZOPFPESXUDBMETSXAIZ
VUEPHZHMDZSHZOWSFPAPDTSVPQUZWYMXUZUHSX
EPYEPOPDZSZUFPOMBZWPFPUPZHMDJUDTMOHMQ

- Count relative letter frequencies

P 13.33	H 5.83	F 3.33	B 1.67	C 0.00
Z 11.67	D 5.00	W 3.33	G 1.67	K 0.00
S 8.33	E 5.00	Q 2.50	Y 1.67	L 0.00
U 8.33	V 4.17	T 2.50	I 0.83	N 0.00
O 7.50	X 4.17	A 1.67	J 0.83	R 0.00
M 6.67				

- Guess P & Z are e and t
- Guess ZW is “th” and hence ZWP is “the”. Frequency of two-letter combinations is known as **digrams**
- Proceeding with trial and error finally get:
**it was disclosed yesterday that several informal but
direct contacts have been made with political
representatives of the viet cong in moscow**

Polyalphabetic Cipher

- ❑ Improve security using multiple cipher alphabets
- ❑ Make cryptanalysis harder with more alphabets to guess and flatter frequency distribution
- ❑ Use a key to select which alphabet is used for each letter of the message
- ❑ Use each alphabet in turn
- ❑ Repeat from start after end of key is reached

Vigenère Cipher

- ❑ Simplest polyalphabetic substitution cipher
- ❑ Effectively **multiple Caesar ciphers**
- ❑ Key is multiple letters long $K = k_1 k_2 \dots k_d$, i^{th} letter specifies i^{th} alphabet to use
- ❑ Use each alphabet in turn
- ❑ Repeat from start after d letters in message
- ❑ Decryption simply works in reverse
- ❑ Write the plaintext out. Write the keyword repeated above it
- ❑ Use each key letter as a Caesar cipher key. Encrypt the corresponding plaintext letter
- ❑ eg using keyword *deceptive*

❑ key:

❑ plaintext:

❑ ciphertext:

d	e	c	e	p	t	i	v	e	d	e	c	e	p	t	i	v	e	d	e	c	e	p	t	i	v	e

Breaking the Vigenère Cipher

- ❑ Have multiple ciphertext letters for each plaintext letter
- ❑ Hence letter frequencies are obscured, but not totally lost
- ❑ Start with letter frequencies
 - ❑ see if look like monoalphabetic or not
- ❑ If not, then need to determine number of alphabets, since then can attach each
- ❑ Kasiski method developed by Babbage/Kasiski is a way of breaking Vigenere
- ❑ Repetitions in ciphertext give clues to period, so find same plaintext an exact period apart which results in the same ciphertext
- ❑ Of course, could also be random fluke
- ❑ eg repeated “VTW” in previous example suggests size of 3 or 9
- ❑ Then attack each monoalphabetic cipher individually using same techniques as before

One-time Pad

- ❑ A random key **as long as the message** is used to encrypt and decrypt a single message
- ❑ The key is then discarded, **never to be used again**
- ❑ The output bears **no statistical relationship** to the plaintext
- ❑ Given any plaintext of equal length to the ciphertext, there is a key that produces that plaintext. Therefore, if you did an exhaustive search of all possible keys, you would end up with many legible plaintexts, with no way of knowing which was the intended plaintext

```
ciphertext: ANKYODKYUREPFJBYOJDSPLREYIUNOFDOIUERFPLUYTS
key:        pxlmvmsydozufyrvzwc tnlebecvgdupahfzzlmnyih
plaintext:  mr mustard with the candlestick in the hall
ciphertext: ANKYODKYUREPFJBYOJDSPLREYIUNOFDOIUERFPLUYTS
key:        mfugpmiydgaxgoufhkl1lmhsqdqogtewbqfgyovuhwt
plaintext:  miss scarlet with the knife in the library
```

- ❑ Large number of keys need to be used. Key distribution is a big problem

Transposition Ciphers

- ❑ Now consider classical **transposition** or **permutation** ciphers
- ❑ These **hide the message by rearranging the letter order** without altering the actual letters used
- ❑ Can recognise these since have the same frequency distribution as the original text
- ❑ Simplest transposition cipher is the **Rail Fence Cipher**
- ❑ Write message letters out diagonally over a number of rows
- ❑ Then read off cipher row by row
- ❑ eg. write message out as:

m e m a t r h t g p r y
e t e f e t e o a a t

- ❑ Giving ciphertext

MEMATRHTGPRYETEFETEOAAT

Row Transposition Ciphers

- ❑ A more complex transposition
- ❑ Write letters of message out in rows over a specified number of columns, then reorder the columns according to some key before reading off the rows

Key:

Plaintext:

4	3	1	2	5	6	7
a	t	t	a	c	k	P
o	s	t	P	o	n	e
d	u	n	t	i	l	t
w	o	a	m	x	y	Z

Ciphertext: TTNAAPTMTSUOAODWCOIXKNLYPETZ

- ❑ Ciphers using substitutions or transpositions are not secure because of language characteristics
- ❑ Hence consider using several ciphers in succession to make harder, but:
 - ❑ two substitutions make a more complex substitution
 - ❑ two transpositions make more complex transposition
 - ❑ but a substitution followed by a transposition makes a new much harder cipher

Rotor Machines

- ❑ Before modern ciphers, rotor machines were most common complex ciphers in use
- ❑ Widely used in WW2
 - ❑ German Enigma, Allied Hagelin, Japanese Purple
- ❑ Implemented a very complex, varying substitution cipher
- ❑ Used a series of cylinders, each giving one substitution, which rotated and changed after each letter was encrypted
- ❑ With 3 cylinders have $26^3=17576$ alphabets

Rotor Machines

Note

The material in this lecture can be found in Chapter 2, Cryptography and network security.
